Abstract: [Authors' English summary modified] Authors re-
port the details of a clinical study on the effectiveness
of Tetracyclinum basicum produced by the Pharmaceutical
Factory Zaklady Farmaceutyczne) in Tarchomin, and compared
it with that of aureo- and terramycin, and report their
findings in five (5) tables. They conclude that tetracyc-
linum basicum is a valuable antibiotic, not worse than
other antibiotics of the tetracycline group. There are 10

2376. THE VALUE OF ANTISTREPTOLYSIN REACTION IN DIFFERENTIAL
DIAGNOSIS OF JOINT DISEASES - Wartość odczynu antystreptolizynowego
w rozpoznaniu różnicowym chorób stawów - Tuszkiewiczowa M.,
Wysokiński Z., and Chariasz S. Zakt. Mikrobiol. Lek., Akad. Med.,
Lublin - POL. ARCH. MED. WEWNĘT. 1958, 28/2 (209-214) Graphs 2 Tables 1

The antistreptolysin level in the blood was determined in 360 persons with diseases in relation to streptococcal infection (rheumatic disease, angina, bronchitis) and with joint diseases of another origin (rheumatoid arthritis, osteoarthritis). In a similar way 120 healthy persons were examined. The mean level of antistreptolysins in healthy persons amounts to 90 U./ml. on the average; it is higher in children in the age of 5-10 yr. than in adults. In rheumatic disease the antistreptolysin level is increasing in children, on the average to 560 U./ml. and in adults to 350 U./ml. In diseases of the joints not connected with the streptococcal infection, the antistreptolysin content in the blood amounts to 120 U./ml. on the average. As the borderline values of the described reaction sometimes show considerable oscillations, they should be evaluated very cautiously, in close connection with the results of other clinical tests.

TITLE: Phenomenon of brucella phage adsorption through chemical brucella substrates

SOURCE: Archiv fur experimentelle Veterinarmedizin, v. 19, no. 4, 1965, 1095-1102

TOPIC TAGS: bacteriophage, virology, bacteriology

ABSTRACT: Acetone substrates of three brucella species (Br. bovis, suis, melitensis) can exert specific inhibition on brucella phage activity. Acetone substrates of other bacterial species do not exert this inhibition. The specificity of this effect was confirmed by experiments with staphylococcus phages which were not inhibited by brucella substrates. The greatest inhibition was exerted by the substrate of Br. suis, the least by Br. melitensis. Inhibition was proportional to the dilution. It is considered probable that Br. melitensis strains contain an antigen substance in their cell wall which serves as receptor of the brucella phages. In the majority of the members this may be localized in the interest of the cells, and yet be potentially present. It seems possible that the dehydration of the cells with acetone and the drying process effects a shifting of these receptors closer to the cell wall. A differentiation of Br. species is not possible by means of this inhibition test since all three inhibit the Br. phage activity. Orig. art. has:

AUTHORS: Tuszyński, Kazimierz; Berka, Mieczysław

TITLE: Mathematical Computers in Chemistry

PERIODICAL: Przemysł Chemiczny, 1960, Vo. 39, No. 11, pp. 684 - 688

TEXT: In this article the authors outline the principles on which the application of analog and digital computers for control of technological processes are based. In the introduction they explain the difference between these two types of computers and what kind of work they can perform. One of the important differences is that for more complicated problems analog computers of larger size have to be used which, however, tend to lose accuracy, while size and properties of digital computers remain stable. At present, mathematical computers are more and more used for calculation of problems in chemical industry. As an example, the authors quote that in the Du Pont Company, USA, about 50% of heat-exchange calculations are performed by such machines. In order to characterise the scope of mathematical computers, the authors list several problems which can be solved by them. Analog computers can deal with problems of sedimentation, mixing of liquids, heat flow, kinetics of chemical reactions, modelling of automatic control circuits, distillation, etc. Digital computers are more universal and can be used for calculation of proc-

Card 1/2

Mathematical Computers in Chemistry

P/014/60/039/011/005/009
A221/A026

esses, installations and even economic problems. They can deal with the following problems: calculation of the minimum degree of "deflagmation" (deflegmacji), chemical equilibria for multi-component systems, thermal cracking of hydrocarbons, alkylation in multi-stage reactors, calculation of distillation columns, reactors, pipe lines, heat exchangers, etc. From these calculations the application of computers for process control was the next logical step. If the machine can calculate in a very short time the optimum value of dependent variables of the process, it is only necessary to adjust the output signals in such a way that they can directly affect the instruments controlling the parameters. The practical application principles are explained. For illustration of such procedures the authors produce two examples, a very simple one, viz. level regulation in a tank, and a more complicated one, viz. an automatic control of a rectification process. In the conclusion the authors point out that computers can be used only if the plant is fully automated beforehand and has an instrument servicing department, capable of maintaining all instruments in excellent working conditions. There are 3 figures and 1 photo.

AUTHOR: Tuszyński, Wacław

TITLE: Shielding Glass Against X-Ray and Gamma-Ray Radiation - Part I

PERIODICAL: Szkło i Ceramika, 1960, No. 11, pp. 321 - 327

TEXT: The author describes the existing theories on the interaction between matter and radiation to derive theoretical and experimental principles for shielding material in general and shielding glass in particular, including the photoelectric absorption process, the scattering of electrons according to the Compton effect and the electron-position pair production. Absorption coefficients are given for lead, aluminum, water etc. Photoelectric absorption coefficients are given for aluminum, iron, tin and lead. Dirac's quantum mechanics theory, the Klein-Nishina scattering formula and Thomson's scattering principle have been used to demonstrate the change of different absorption coefficients depending on the energy of various elements. There are 7 figures and 2 tables. (To be continued). X

AUTHOR: Tuszyński, Wacław

TITLE: Shielding Glass Against X-Ray and Gamma-Ray Radiation - Part II

PERIODICAL: Szkło i Ceramika, 1960, No. 12, pp. 353 - 360

TEXT: The author lists a number of formulae derived by J.A. Victoreen, F. Brewster and J. Kreidl, and also methods elaborated by the above scientists which permit to calculate the absorption coefficient of various oxides used in the production of x-ray and gamma-ray radiation shielding glass. Further he describes the properties of x-ray and gamma-ray radiation shielding glass produced by the West German firm "Schott". The author concludes that the computation method for the lead equivalent is sufficient to determine the chemical composition of glass with optional lead equivalent, provided the degree of x-ray and gamma-ray radiation energy is known. The chemical composition of glass established by this method meets technological and lead-equivalent specifications. Proper control of raw materials and chemical combination will allow a reduction in thickness of glass plates. Such glass may also be used in nuclear engineering. There are 10 tables, 8 figures and 12 references: 4 Polish, 1 Czech, 2 Soviet, 4 English and 1 German.

AUTHORS: Kopiński, Jerzy, and Tuszko, Aleksander

TITLE: On the organization of research and planning problems
in the USSR

PERIODICAL: Nauka Polska, no. 3, 1960, 152-172

TEXT: In this article the authors present their own impressions and observations perceived as the result of personal contacts with representatives of central and regional Soviet scientific bodies during their official visit to the USSR. The most vivid impression which struck the authors is the extensive cooperation between science and the producing industry. In 1959 there were about 3,200 scientific outposts and institutions in the USSR employing about 300,000 scientific workers. About 50% of them were employed by scientific research institutes and 140,000 by 800 university-type schools. Scientific outposts in the USSR are grouped around: (1) The USSR Academy of Sciences, which is the highest scientific authority in the country; (2) University-level schools; (3) Industry.

Card 1/7

On the organization of research...

P/002/60/000/003/002/003
D001/D101

The largest organization is the Academy; it employs about 20% of all scientists in the USSR including over 400 academy members (academicians) and about 18,000 scientific workers appointed to over 200 Academy scientific outposts. Apart from the USSR Academy, there are also Academies of Sciences in the 13 republics forming the Soviet Union with about 750 academicians and 10,000 scientific workers. Medicine, agriculture, and building and architectural problems are dealt with by respective separate academies, employing jointly about 14,000 scientists. The USSR Academy working plan includes about 5,000 items, of which an integral part consisted of about 90 problems of principal importance and of which 30 were selected as the leading ones. The second group comprises the university-level schools which employ about 140,000 scientific workers of which 45% have scientific titles or degrees. Research laboratories of this group solved about 30,000 research problems in 1959, of which 1,500 were classified as important. Three hundred problems of particular importance for the national economy were investigated on government request. The third group of research institutions comprises the industrial scientific institutes, called "branch institutes",

On the organization of research... D001/D101

tackling problems concerning mainly the respective branches of industry. These institutes employ about 25% of the total number of scientific workers available in the USSR and many thousands of engineers, designers, technologists, etc., as well. It is difficult to present more accurate figures concerning this group, because, following the reorganization of some ministries in the USSR a few years ago, these institutions too, are actually in the state of reorganization. These outposts are now subordinate either to the scientific-technical branch committees (like the Automation and Machine Construction Committee, Chemistry Committee, Radioelectronics Committee, etc.), to the USSR and Republic Planning Commissions or to the National Economy Councils. The USSR Planning Commission employs about 20,000 scientific workers and the Committee for Chemistry also about 20,000, and so on. In general, all these institutions have their own design and technological offices and in the majority of cases workshops and prototype experimental laboratories as well. One can assume that all scientific outposts in the USSR employ (including technicians and auxiliary assistants) over a million scientific workers. There are two main tendencies in establishing ✓

D001/D101

On the organization of research...

the Academy of Sciences' trend of work. Industry advocates a more practical approach to problems by asking for ready-made standards, prototypes and processes directly applicable in industry; the other tendency backs new lines of theoretical research on basically important problems. As to research carried out within industry, the tendency prevails to join small individual plant laboratories into large, well-equipped research institutes. Planning and coordination of research work is carried out in the USSR on an established pattern. Each problem which is to be investigated is clearly defined and its reason and practical usefulness explained. For instance, the problem is as follows: To examine metal flow at 600-800°C. The purpose of this research project is to select materials for gas- and steam turbines which will be working at 600-800°C. Investigation plans are worked out in a series of standard stages as follows: (1) General investigation of the problem including an analysis of the actual state of knowledge concerning this problem both at home and abroad; (2) Preparation of theoretical and practical investigation and experimentation program and suggesting the

Card 4/7

On the organization of research...

P/002/60/000/003/002/003

D001/D101

method which will have to be applied; (3) Carrying out the proposed theoretical, experimental and technical-economic investigation; (4) Designs for the construction of prototypes and models of automation equipment, installations and apparatus; (5) Testing of the above-mentioned assemblies; (6) Working out the specification or documentation for serial production of new systems of automation or new devices, and introduction into practice; (7) Checking of the technical economic effectiveness and preparing the final report for publication. Directives for carrying out research on the most important problems are sanctioned by the USSR Council of Ministers. An annual report of completed research work is sent back to the Planning Commission and Scientific Technical Committee which recommend them for industrial exploitation. If the problem is a complicated one and can't be solved by one institution, it is one of the Academy of Sciences' duties to coordinate research carried out by its various outposts. In particularly important cases, the Academy convenes scientific coordinating councils including representatives of universities, industrial institutes and industry. Research on polymers, for instance, is carried out by 150 outposts, subordinate to the

D001/D101

USSR Academy of Sciences, Republic Academies, Ministry of Higher Education, the Committee for Chemistry and 124 central industrial plant laboratories, subordinate to several Councils of National Economy. One of the basic conditions for the proper functioning of research is the knowledge of scientific progress achieved by the USSR and foreign research institutions. This is looked after by a widely-branched information service carried out by Vsesoyuznyy Institut Nauchnoy i Tekhnicheskoy Informatsii (All-Union Institute of Scientific and Technical Information) "VINITI" for short, subordinate to the USSR Academy of Sciences and the Gosudarstvennyy Nauchno-Tekhnicheskiy Komitet (State Scientific-Technical Committee) "GNTK" for short. Its publication the "Referativnyi Zhurnal" (Reference Journal) is the most complete source of the world's research documentation. In order to maintain a high caliber of the institutes' workers, a suggestion was put forward that one half of all posts should be gradually filled by the most capable university graduates and engineers designated by industry. After three years probationary period only 10-15% of the very best would be retained and the remainder

Card 6/7

P/002/60/000/003/002/003
On the organization of research... D001/D101

replaced by a new influx; the 85-90% rejected persons would be redirected to industrial institutes for less important work. Following names of USSR scientists are mentioned in this article: Academicians N. N. Syemyonov, Secretary of Chemistry Department of the USSR Academy of Sciences, A. Blagovorov, I. Arbolevskiy, A. Minc, B. Stechkov, Corresponding member of the Academy, A. Kursh, Professor at Moscow University, and Elyutin, Minister of Higher Education. There are 2 Soviet references.

It is suggested that, to prevent stoppages in processing plants,
specially arranged dumps should be used instead of bins for storing
coal. The dumps are divided into three sections adapted respectively to
short, medium and long storing of coal. The arrangement of dumps,
their size, and their layout in relation to the layout of the processing
plant are discussed together with advantages and disadvantages.

Tuzyńska S., Myszkowska K., Wrzosek W., Lewandowska K. Microbiological Method of Determining Vitamin B₆ in Multivitamin Preparations

Mikrobiologiczna metoda oznaczania witaminy B₆ w preparatach wielowitaminowych. "Przemysł Chemiczny" Nr. 11 1954, pp. 577-578
1 fig., 1 tab.

A microbiological method of determining vitamin B₆ complex in multivitamin preparations, using *Saccharomyces carlsbergensis* 4228 on the basis of the Atkin test. How to prepare casein hydrolysate free of vita-

min B₆ using ultraviolet rays is described together with optimal concentration of strain dispersion and the technique of homogeneous inoculation. As a means of saturating with oxygen, uniform shaking of samples was performed at constant temperature. This method makes it possible to determine the vitamin B₆ in multivitamin preparations containing large quantities of vitamin B (thiamine).

tion of Folic Acid by the Use of *Streptococcus faecalis*. R.
R. P. Preprint. Chemia, No. 2, 1964, pp. 93-96. Leningrad.

The authors have developed a method for the detection of folic acid based on the use of *Streptococcus faecalis*. The method is based on the fact that *S. faecalis* can utilize folic acid as a sole source of folate. The method involves the growth of *S. faecalis* in a medium containing folic acid as the sole source of folate. The growth of the bacteria is monitored by measuring the optical density of the culture at a wavelength of 540 nm. The method is sensitive enough to detect folic acid at concentrations as low as 10^-12 M.
